Package 'rcss'

September 13, 2017

Type Package
Title Convex Switching Systems
Version 1.5
Date 2017-10-11
Author Juri Hinz and Jeremy Yee
Maintainer Jeremy Yee <jeremyyee@outlook.com.au></jeremyyee@outlook.com.au>
Description The numerical treatment of optimal switching problems in a finite time setting when the state evolves as a controlled Markov chain consisting of a uncontrolled continuous component following linear dynamics and a controlled Markov chain taking values in a finite set. The reward functions are assumed to be convex and Lipschitz continuous in the continuous state. The action set is finite.

Description

Approximate the value functions using k nearest neighbours.

Usage

AcceleratedBellman(grid, reward, scrap, control, disturb, weight, k = 1)

Arguments

grid	Matrix representing the grid. The i-th row corresponds to i-th point of the grid. The j-th column captures the dimensions. The first column must equal to 1.
reward	5-D array representing the tangent approximation of the reward. Entry [i,,a,p,t] captures the tangent at grid point i for action a taken in position p at time t. The intercept is given by [i,1,a,p,t] and slope by [i,-1,a,p,t].
scrap	4-D array representing the tangent approximation of the scrap. Entry [i,,p,t] captures the tangent at grid point i for position p. The intercept is given by [i,1,a,p] and slope by [i,-1,a,p].
control	Array representing the transition probabilities of the controlled Markov chain. Two possible inputs:
	• Matrix of dimension $n_pos \times n_action$, where entry [i,j] describes the next position after selecting action j at position i.
	• 3-D array with dimensions n_pos × n_action × n_pos, where entry [i,j,k] is the probability of moving to position k after applying action j to position i.
disturb	3-D array containing the disturbance matrices. Matrix ["i] specifies the i-th disturbance matrix.
weight	Array containing the probability weights of the disturbance matrices.
k	Number of nearest neighbours used for each grid point.

AcceleratedExpected 3

Value

value 4-D array tangent approximation of the value function, where the intercept [i,1,p,t]

and slope [i,-1,p,t] describes a tangent of the value function at grid point i for

position p at time t.

expected 4-D array representing the expected value functions.

Author(s)

Jeremy Yee

Examples

```
## Bermuda put option
grid <- as.matrix(cbind(rep(1, 81), c(seq(20, 60, length = 81))))</pre>
disturb <- array(0, dim = c(2, 2, 100))
disturb[1, 1,] <- 1
quantile <- qnorm(seq(0, 1, length = (100 + 2))[c(-1, -(100 + 2))])
disturb[2, 2,] <- exp((0.06 - 0.5 * 0.2^2) * 0.02 + 0.2 * sqrt(0.02) * quantile)
weight <- rep(1 / 100, 100)
control <- matrix(c(c(1, 2), c(1, 1)), nrow = 2)
reward <- array(data = 0, dim = c(81, 2, 2, 50))
in_money <- grid[, 2] <= 40</pre>
reward[in_money, 1, 2, 2,] <- 40</pre>
reward[in_money, 2, 2, 2,] <- -1
for (tt in 1:50){
  reward[,,2,2,tt] \leftarrow exp(-0.06 * 0.02 * (tt - 1)) * reward[,,2,2,tt]
}
scrap \leftarrow array(data = 0, dim = c(81, 2, 2))
scrap[in\_money, 1, 2] <- 40
scrap[in\_money, 2, 2] <- -1
scrap[,,2] \leftarrow exp(-0.06 * 0.02 * 50) * scrap[,,2]
bellman <- AcceleratedBellman(grid, reward, scrap, control, disturb, weight)</pre>
```

AcceleratedExpected

Expected value function using k nearest neighbours

Description

Approximate the expected value function using k nearest neighbours.

Usage

```
AcceleratedExpected(grid, value, disturb, weight, k = 1)
```

Arguments

grid	Matrix representing the grid. The i-th row corresponds to i-th point of the grid. The j-th column captures the dimensions. The first column must equal to 1.
value	Matrix representing the tangent approximation of the future value function, where the intercept [i,1] and slope [i,-1] describes a tangent at grid point i.
disturb	3-D array containing the disturbance matrices. Matrix [,,i] specifies the i-th disturbance matrix.
weight	Array containing the probability weights of the disturbance matrices.
k	Number of nearest neighbours used for each grid point.

Value

Matrix representing the tangent approximation of the expected value function. Same format as the value input.

AddDual 5

	Additive duals	AddDual
--	----------------	---------

Description

Additive duals by comparing all tangents.

Usage

```
AddDual(path, subsim, weight, value, Scrap)
```

Arguments

path	3-D array representing sample paths. Entry $[i,j]$ represents the state at time j for sample path i .
subsim	5-D array containing the subsimulation disturbance matrices. Matrix $[,i,j,t]$ represents the disturbance used in subsimulation i on sample path j at time t.
weight	Array specifying the probability weights of the subsimulation disturbance matrices.
value	4-D array tangent approximation of the value function, where the intercept $[i,1,p,t]$ and slope $[i,-1,p,t]$ describes a tangent of the value function at grid point i for position p at time t .
Scrap	User supplied function to represent the scrap function. The function should take in the following argument:
	• $n \times d$ matrix representing the n d -dimensional states.

The function should output the following:

• Matrix with dimensions $n \times p$) representing the scraps, where p is the number of positions. The [i,p]-th entry corresponds to the scrap at the p-th position for the i-th state.

Value

3-D array where entry [i,p,t] represents the martingale increment at time t for position p on sample path i.

AddDualBounds 7

Description

Bound estimates using the additive duals.

Usage

AddDualBounds(path, control, Reward, Scrap, dual, policy)

Arguments

path

3-D array representing sample paths. Entry [i,,j] represents the state at time j for sample path i.

control

Array representing the transition probabilities of the controlled Markov chain. Two possible inputs:

- Matrix of dimension n_pos × n_action, where entry [i,j] describes the next position after selecting action j at position i.
- 3-D array with dimensions n_pos × n_action × n_pos, where entry [i,j,k] is the probability of moving to position k after applying action j to position i

Reward

User supplied function to represent the reward function. The function should take in the following arguments, in this order:

- $n \times d$ matrix representing the n d-dimensional states.
- A natural number representing the decison epoch.

The function should output the following:

3-D array with dimensions n × (a × p) representing the rewards, where p is
the number of positions and a is the number of actions in the problem. The
[i, a, p]-th entry corresponds to the reward from applying the a-th action to
the p-th position for the i-th state.

Scrap

User supplied function to represent the scrap function. The function should take in the following argument:

• $n \times d$ matrix representing the n d-dimensional states.

The function should output the following:

• Matrix with dimensions $n \times p$) representing the scraps, where p is the number of positions. The [i,p]-th entry corresponds to the scrap at the p-th position for the i-th state.

dual

3-D array where entry [i,p,t] represents the additive dual at time t for position p on sample path i.

policy

3-D array representing the prescribed policy for the sample paths. Entry [i,p,t] gives the prescribed action at time t for position p on sample path t.

Value

List containing:

primal

3-D array representing the primal values, where entry [i,p,t] represents the value at time t for position p on sample path i.

dual

3-D array representing the dual values. Same format as above.

Bellman 9

Bellman Bellman recursion

Description

Approximate the value functions by comparing all tangents.

Usage

```
Bellman(grid, reward, scrap, control, disturb, weight)
```

Ar

Arguments	
grid	Matrix representing the grid. The i-th row corresponds to i-th point of the grid. The j-th column captures the dimensions. The first column must equal to 1.
reward	5-D array representing the tangent approximation of the reward. Entry [i,,a,p,t] captures the tangent at grid point i for action a taken in position p at time t. The intercept is given by [i,1,a,p,t] and slope by [i,-1,a,p,t].
scrap	4-D array representing the tangent approximation of the scrap. Entry [i,,p,t] captures the tangent at grid point i for position p. The intercept is given by [i,1,a,p] and slope by [i,-1,a,p].
control	Array representing the transition probabilities of the controlled Markov chain. Two possible inputs:
	• Matrix of dimension $n_pos \times n_action$, where entry [i,j] describes the next position after selecting action j at position i.
	• 3-D array with dimensions n_pos × n_action × n_pos, where entry [i,j,k] is the probability of moving to position k after applying action j to position i.
disturb	3-D array containing the disturbance matrices. Matrix [,,i] specifies the i-th disturbance matrix.
weight	Array containing the probability weights of the disturbance matrices.
Value	
value	4-D array tangent approximation of the value function, where the intercept [i,1,p,t] and slope [i,-1,p,t] describes a tangent of the value function at grid point i for position p at time t.
expected	4-D array representing the expected value functions.

```

Expected

Expected value function

Description

Approximate the expected value function by comparing all tangents.

Usage

```
Expected(grid, value, disturb, weight)
```

Arguments

grid	Matrix representing the grid. The i-th row corresponds to i-th point of the grid. The j-th column captures the dimensions. The first column must equal to 1.
value	Matrix representing the tangent approximation of the future value function, where the intercept [i,1] and slope [i,-1] describes a tangent at grid point i.
disturb	3-D array containing the disturbance matrices. Matrix [,,i] specifies the i-th disturbance matrix.
weight	Array containing the probability weights of the disturbance matrices.

Value

Matrix representing the tangent approximation of the expected value function. Same format as the value input.

FastAddDual

Fast additive duals

Description

Additive duals using nearest neighbours.

Usage

```
FastAddDual(path, subsim, weight, grid, value, Scrap)
```

Arguments

path	3-D array representing sample paths. Entry $[i,j]$ represents the state at time j for sample path i .
subsim	5-D array containing the subsimulation disturbance matrices. Matrix $[,,i,j,t]$ represents the disturbance used in subsimulation i on sample path j at time t.
weight	Array specifying the probability weights of the subsimulation disturbance matrices.
grid	Matrix representing the grid. The i-th row corresponds to i-th point of the grid. The j-th column captures the dimensions. The first column must equal to 1.

12 FastAddDual

value

4-D array tangent approximation of the value function, where the intercept [i,1,p,t] and slope [i,-1,p,t] describes a tangent of the value function at grid point i for position p at time t.

Scrap

User supplied function to represent the scrap function. The function should take in the following argument:

• $n \times d$ matrix representing the n d-dimensional states.

The function should output the following:

• Matrix with dimensions $n \times p$) representing the scraps, where p is the number of positions. The [i,p]-th entry corresponds to the scrap at the p-th position for the i-th state.

Value

3-D array where entry [i,p,t] represents the martingale increment at time t for position p on sample path i.

FastBellman

Fast Bellman Recursion

Description

Approximate the value functions using conditional expectation matrices

Usage

Arguments

grid	Matrix representing the grid. The i-th row corresponds to i-th point of the grid. The j-th column captures the dimensions. The first column must equal to 1.
reward	5-D array representing the tangent approximation of the reward. Entry [i,,a,p,t] captures the tangent at grid point i for action a taken in position p at time t. The intercept is given by [i,1,a,p,t] and slope by [i,-1,a,p,t].
scrap	4-D array representing the tangent approximation of the scrap. Entry [i,,p,t] captures the tangent at grid point i for position p. The intercept is given by [i,1,a,p] and slope by [i,-1,a,p].
control	Array representing the transition probabilities of the controlled Markov chain. Two possible inputs:

14 FastBellman

• Matrix of dimension n_pos × n_action, where entry [i,j] describes the next position after selecting action j at position i.

3-D array with dimensions n_pos × n_action × n_pos, where entry [i,j,k] is the probability of moving to position k after applying action j to position i.

disturb

3-D array containing the disturbance matrices. Matrix [,,i] specifies the i-th disturbance matrix.

weight

Array containing the probability weights of the disturbance matrices.

r_index

Matrix representing the positions of random entries in the disturbance matrix, where entry [i,1] is the row number and [i,2] gives the column number of the i-th random entry.

smooth

The number of nearest neighbours used to smooth the expected value functions during the Bellman recursion.

Value

value

4-D array tangent approximation of the value function, where the intercept [i,1,p,t] and slope [i,-1,p,t] describes a subgradient of the value function at grid point i for position p at time t.

expected

4-D array representing the expected value functions.

```

FastExpected 15

FastExpected	Fast expected value function	

Description

Approximate the expected value function using conditional expectaion matrices.

Usage

```
FastExpected(grid, value, disturb, weight, r_index, smooth = 1)
```

Arguments

grid	Matrix representing the grid. The i-th row corresponds to i-th point of the grid. The j-th column captures the dimensions. The first column must equal to 1.
value	Matrix representing the tangent approximation of the future value function, where the intercept [i,1] and slope [i,-1] describes a tangent at grid point i.
disturb	3-D array containing the disturbance matrices. Matrix [,,i] specifies the i-th disturbance matrix.
weight	Array containing the probability weights of the disturbance matrices.
r_index	Matrix representing the positions of random entries in the disturbance matrix, where entry [i,1] is the row number and [i,2] gives the column number of the i-th random entry.
smooth	The number of nearest neighbours used to smooth the expected value functions during the Bellman recursion.

Value

Matrix representing the tangent approximation of the expected value function. Same format as the value input.

```

FastPathPolicy

Fast prescribed policy

Description

Policy precribed to provided sample paths using nearest neighbours

Usage

FastPathPolicy(path, grid, control, Reward, expected)

Arguments

path

3-D array representing sample paths. Entry [i,,j] represents the state at time j for sample path i.

grid

Matrix representing the grid. The i-th row corresponds to i-th point of the grid. The j-th column captures the dimensions. The first column must equal to 1.

control

Array representing the transition probabilities of the controlled Markov chain. Two possible inputs:

- Matrix of dimension $n_{pos} \times n_{action}$, where entry [i,j] describes the next position after selecting action j at position i.
- 3-D array with dimensions $n_pos \times n_action \times n_pos$, where entry [i,j,k]is the probability of moving to position k after applying action j to position i.

Reward

User supplied function to represent the reward function. The function should take in the following arguments, in this order:

- $n \times d$ matrix representing the n d-dimensional states.
- A natural number representing the decison epoch.

The function should output the following:

• 3-D array with dimensions $n \times (a \times p)$ representing the rewards, where p is the number of positions and a is the number of actions in the problem. The [i, a, p]-th entry corresponds to the reward from applying the a-th action to the p-th position for the i-th state.

FastPathPolicy 17

expected

4-D array representing the tangent approximation of the expected value function, where the intercept [i,1,p,t] and slope [i,-1,p,t] describes a tangent at grid point i for position p at time t.

Value

3-D array representing the prescribed policy for the sample paths. Entry [i,p,t] gives the prescribed action at time t for position p on sample path t.

18 FiniteAddDual

FiniteAddDual Finite distribution case additive duals

Description

Additive duals for finite distribution case. No nested simulation.

Usage

```
FiniteAddDual(path, disturb, grid, value, expected, build = "fast", k = 1)
```

Arguments

path	3-D array representing sample paths. Entry [i,j] represents the state at time j for sample path i.
disturb	4-D array containing the disturbances used to generate the paths. Matrix [,,i,t] represents the disturbance at time t for sample path i.
grid	Matrix representing the grid. The i-th row corresponds to i-th point of the grid. The j-th column captures the dimensions. The first column must equal to 1.
value	4-D array tangent approximation of the value function, where the intercept [i,1,p,t] and slope [i,-1,p,t] describes a tangent of the value function at grid point i for position p at time t.
expected	4-D array representing the tangent approximation of the expected value function, where the intercept [i,1,p,t] and slope [i,-1,p,t] describes a tangent at grid point i for position p at time t.
build	string indicating which build method used to obtain expected value functions: "fast", "accelerated", and "slow".
k	Number of nearest neighbours used for "accelerated" build.

Value

3-D array where entry [i,p,t] represents the martingale increment at time t for position p on sample path i.

FullTestPolicy

Full backtesting prescribed policy

Description

Backtesting prescribed policy with value, position, action evolution.

Usage

```
FullTestPolicy(position, path, control, Reward, Scrap, policy)
```

20 FullTestPolicy

Arguments

position

Natural number indicating the starting position.

path

3-D array representing sample paths. Entry [i,,j] represents the state at time j for sample path i.

control

Array representing the transition probabilities of the controlled Markov chain. Two possible inputs:

- Matrix of dimension $n_pos \times n_action$, where entry [i,j] describes the next position after selecting action j at position i.
- 3-D array with dimensions n_pos × n_action × n_pos, where entry [i,j,k] is the probability of moving to position k after applying action j to position i.

Reward

User supplied function to represent the reward function. The function should take in the following arguments, in this order:

- $n \times d$ matrix representing the n d-dimensional states.
- A natural number representing the decison epoch.

The function should output the following:

3-D array with dimensions n × (a × p) representing the rewards, where p is
the number of positions and a is the number of actions in the problem. The
[i, a, p]-th entry corresponds to the reward from applying the a-th action to
the p-th position for the i-th state.

Scrap

User supplied function to represent the scrap function. The function should take in the following argument:

• $n \times d$ matrix representing the n d-dimensional states.

The function should output the following:

• Matrix with dimensions $n \times p$) representing the scraps, where p is the number of positions. The [i,p]-th entry corresponds to the scrap at the p-th position for the i-th state.

policy

3-D array representing the prescribed policy for the sample paths. Entry [i,p,t] gives the prescribed action at time t for position p on sample path t.

Value

value

Matrix containing the backtesting values for each sample path. Entry[i,t] refers to the value at time t for sample path i.

position

Matrix containing the evolution of the position. Entry[i,t] refers to the position at time t for sample path i.

action

Matrix containing the actions taken. Entry[i,t] refers to the action at time t for sample path i.

GetBounds

Confidence Bounds

Description

Confidence bounds for the value.

22 GetBounds

Usage

```
GetBounds(duality, alpha, position)
```

Arguments

duality Object returned by the Duality function.

alpha Specifies the (1-alpha) confidence bounds.

position Natural number indicating the starting position.

Value

Array representing the (1-alpha) confidence bounds for the value of the specified position.

Author(s)

Jeremy Yee

Optimal

Optimal

Description

Find the maximising tangent at each grid point.

Usage

```
Optimal(grid, tangent)
```

Arguments

grid Matrix representing the grid. The i-th row corresponds to i-th point of the grid.

The j-th column captures the dimensions. The first column must equal to 1.

tangent Matrix representing the collection of tangents, where the intercept [i,1] and slope

[i,-1] describes a tangent at grid point i.

Value

Matrix representing the maximum of the tangents at each grid point, where the intercept [i,1] and slope [i,-1] describes the maximising tangent at grid point i.

Author(s)

Jeremy Yee

```
grid <- as.matrix(cbind(rep(1, 81), c(seq(20, 60, length = 91))))
tangent <- matrix(rnorm(81 * 2), ncol = 2)
Optimal(grid, tangent)</pre>
```

24 PathPolicy

PathPolicy

Prescribed policy

Description

Policy prescribed to provided sample paths

Usage

PathPolicy(path, control, Reward, expected)

Arguments

path

3-D array representing sample paths. Entry [i,j] represents the state at time j for sample path i.

control

Array representing the transition probabilities of the controlled Markov chain. Two possible inputs:

- Matrix of dimension n_pos × n_action, where entry [i,j] describes the next position after selecting action j at position i.
- 3-D array with dimensions n_pos × n_action × n_pos, where entry [i,j,k] is the probability of moving to position k after applying action j to position i.

Reward

User supplied function to represent the reward function. The function should take in the following arguments, in this order:

- $n \times d$ matrix representing the n d-dimensional states.
- A natural number representing the decison epoch.

The function should output the following:

3-D array with dimensions n × (a × p) representing the rewards, where p is
the number of positions and a is the number of actions in the problem. The
[i, a, p]-th entry corresponds to the reward from applying the a-th action to
the p-th position for the i-th state.

expected

4-D array representing the tangent approximation of the expected value function, where the intercept [i,1,p,t] and slope [i,-1,p,t] describes a tangent at grid point i for position p at time t.

Value

3-D array representing the prescribed policy for the sample paths. Entry [i,p,t] gives the prescribed action at time t for position p on sample path t.

Author(s)

StochasticGrid

Stochastic grid

Description

Generate a grid using k-means clustering.

Usage

```
StochasticGrid(path, n_grid, max_iter, warning)
```

26 TestPolicy

Arguments

path 3-D array representing sample paths. Entry [i,,j] represents the state at time j for

sample path i.

n_grid Number of grid points in the stochastic grid.

max_iter Maximum iterations in the k-means clustering algorithm.

warning Boolean indicating whether messages from the k-means clustering algorithm are

to be displayed

Value

Matrix representing the stochastic grid. Each row represents a particular grid point. The first column contains only 1.

Author(s)

Jeremy Yee

Examples

```
## Generate paths
start <- c(1, 36)
path_disturb <- array(0, dim = c(2, 2, 100, 50))
path_disturb[1, 1,,] <- 1
rand1 <- rnorm((50 * 100) / 2)
rand1 <- as.vector(rbind(rand1, -rand1))
path_disturb[2, 2,,] <- exp((0.06 - 0.5 * 0.2^2) * 0.02 + 0.2 * sqrt(0.02) * rand1)
path <- PathDisturb(start, path_disturb)
sgrid <- StochasticGrid(path, 81, 10)</pre>
```

TestPolicy

Backtesting Prescribed policy

Description

Backtesting prescribed policy.

Usage

```
TestPolicy(position, path, control, Reward, Scrap, policy)
```

Arguments

position Natural number indicating the starting position.

path 3-D array representing sample paths. Entry [i,,j] represents the state at time j for

sample path i.

control Array representing the transition probabilities of the controlled Markov chain.

Two possible inputs:

TestPolicy 27

- Matrix of dimension $n_{pos} \times n_{action}$, where entry [i,j] describes the next position after selecting action j at position i.
- 3-D array with dimensions $n_pos \times n_action \times n_pos$, where entry [i,j,k]is the probability of moving to position k after applying action j to position

Reward

User supplied function to represent the reward function. The function should take in the following arguments, in this order:

- $n \times d$ matrix representing the n d-dimensional states.
- A natural number representing the decison epoch.

The function should output the following:

• 3-D array with dimensions $n \times (a \times p)$ representing the rewards, where p is the number of positions and a is the number of actions in the problem. The [i, a, p]-th entry corresponds to the reward from applying the a-th action to the p-th position for the i-th state.

Scrap

User supplied function to represent the scrap function. The function should take in the following argument:

• $n \times d$ matrix representing the n d-dimensional states.

The function should output the following:

• Matrix with dimensions $n \times p$) representing the scraps, where p is the number of positions. The [i, p]-th entry corresponds to the scrap at the p-th position for the i-th state.

policy

3-D array representing the prescribed policy for the sample paths. Entry [i,p,t] gives the prescribed action at time t for position p on sample path t.

Value

Array containing the backtesting values for each sample path.
